1 Introduction

The first part of this text is primarily concerned with the solutions to differential equations of the form

$$\mathbf{L}u = \phi \quad (1.1)$$

over an interval $a \leq x \leq b$ and subject to certain boundary conditions, where \mathbf{L} is an n th order linear ordinary differential operator, where the function ϕ is integrable on the given interval. For \mathbf{L} to be linear, it must satisfy the condition

$$\mathbf{L}(\alpha v + \beta w) = \alpha \mathbf{L}v + \beta \mathbf{L}w \quad (1.2)$$

for arbitrary functions v and w , with α and β being constant. We claim without proof that for this condition to be met, \mathbf{L} must be of the form

$$\mathbf{L} = a_0(x) \frac{d^n}{dx^n} + a_1(x) \frac{d^{n-1}}{dx^{n-1}} + \cdots + a_n(x). \quad (1.3)$$

Since \mathbf{L} is of order n , there will be n boundary conditions of the general form

$$B_j(u) = c_j; \quad j = 1, 2, \dots, n \quad (1.4)$$

where the B_j 's are prescribed functionals and c_j 's are prescribed constants. We will only consider B_j 's that are linear combinations of u and its derivatives through order $n - 1$ and evaluated at the endpoints, a and b .

A functional is a transformation with a set of functions as its domain and a set of numbers as its range. To illustrate, consider the functional

$$\mathcal{F}(u) = \int_0^1 u^2(x) dx. \quad (1.5)$$

The domain of this functional might be the set of functions defined over the interval $(0, 1)$ and for which the integral of u^2 from 0 to 1 exists, and the range is $(0, \infty)$.

For B_j to be linear, it must satisfy the condition

$$B_j(\alpha v + \beta w) = \alpha B_j(v) + \beta B_j(w) \quad (1.6)$$

2 The Adjoint Operator

To determine the Green's function for a particular differential equation and its boundary conditions, begin by finding the adjoint operator, denoted \mathbf{L}^* . The adjoint operator consists of the formal adjoint, \mathbf{L}^* , and the boundary conditions associated with the Green's function. To determine these, first form the product, vLu , and integrate it over the interval of interest. By repeated integration by parts, we can express the integral in the form

$$\int_a^b vLudx = \left[\cdots \right] \Big|_a^b + \int_a^b u\mathbf{L}^*vdx, \quad (2.1)$$

where $[\dots] \Big|_a^b$ represents the boundary terms resulting from the successive integration by parts. Here, u and v must be sufficiently differentiable functions so that the left and right sides are well defined.

As an example, consider the linear differentiable operator

$$L = a(x) \frac{d^2}{dx^2} + b(x) \frac{d}{dx} + c(x) \quad (2.2)$$

To find \mathbf{L}^* , perform integration by parts on each term of the product vLu until there is no derivative of u within the integral. That is to say, integrate by parts twice on the first term, once on the second, and not at all on the third. Doing this, we are left with

$$\begin{aligned} \int_a^b vLu dx &= \int_a^b (vau'' + vbu' + vc) dx \\ &= (vau' + vbu) \Big|_a^b + \int_a^b (-(va)'u' - (vb)'u + vcu) dx \\ &= (vau' + vbu - (va)'u) \Big|_a^b + \int_a^b ((va)''u - (vb)'u + vcu) dx \\ &= (vau' + vbu - (va)'u) \Big|_a^b + \int_a^b u((va)'' - (bv)' + cv) dx. \end{aligned} \quad (2.3)$$

From this, it is clear that

$$\begin{aligned} \mathbf{L}^*v &= (av)'' - (bv)' + cv \\ &= (a'v + av')' - b'v - bv' + cv \\ &= av'' + (2a' - b)v' + (a'' - b' + c)v \end{aligned} \quad (2.4)$$

and so the formal adjoint of the second-order linear differential operator L must be of the form

$$\mathbf{L}^* = a \frac{d^2}{dx^2} + (2a' - b) \frac{d}{dx} + (a'' - b' + c). \quad (2.5)$$

If $\mathbf{L}^* = L$, then L is called formally self-adjoint. By comparing equations (2.2) and (2.5), we can see that for a second-order linear differentiable operator to be formally self-adjoint, it is sufficient that $a' = b$. You may notice that $a'' - b' + c$ must also be equal to C , but this is always true given that a' equals b .

Definition If the boundary conditions on L are homogeneous¹, then we can also define an adjoint operator, \mathcal{L}^* , by the relation

$$(Lu, v) = (u, \mathbf{L}^*v) \quad (2.6)$$

where (f, g) is the inner product of f and g ,

$$(f, g) = \int_a^b f(x)g(x)dx. \quad (2.7)$$

This means that the adjoint operator \mathcal{L}^* consists of \mathbf{L}^* and boundary conditions for which the boundary terms of the integral are zero.

¹By homogeneous, we mean that each boundary condition is of the form $B_j(u) = 0$.

Example 2.1 Consider \mathcal{L} to consist of $L = \frac{d}{dx}$ and the boundary condition $u(0) = 3u(1)$ over the interval $0 \leq x \leq 1$. Then

$$\begin{aligned}
(Lu, v) &= \int_0^1 u'v dx \\
&= (uv) \Big|_0^1 - \int_0^1 uv' dx \\
&= u(1)v(1) - u(0)v(0) + \int_0^1 u\mathbf{L}^*v dx \\
&= u(1)(v(1) - 3v(0)) + \int_0^1 u\mathbf{L}^*v dx
\end{aligned} \tag{2.8}$$

Since the particular value of $u(1)$ is not given, we must impose the condition $v(1) - 3v(0) = 0$, because choosing $u(1) = 0$ would unduly restrict our solution. Therefore \mathbf{L}^* consists of \mathbf{L}^* which is $-\frac{d}{dx}$ and the boundary condition $v(1) - 3v(0) = 0$.

As a final note, if $\mathcal{L} = \mathcal{L}^*$, then \mathcal{L} is called self-adjoint.

3 The Delta Function

3.1 Delta Sequences

In physics, we often consider the idea of a point mass. Suppose we have a unit point mass with mass density given by $w(x)$. We are interested in the mass but do not know the details of its density. We do, however, know that the $w(x)$ will be highly localized in space and that

$$\int_{-\infty}^{\infty} w(x) dx = 1 \tag{3.1}$$

so that the net mass is unity.

We expect two highly concentrated unit mass densities to produce nearly identical masses. As such, we might simplify the problem by deciding, a priori, on a definite form for w , such as

$$w_k(x) = \begin{cases} \frac{k}{2}, & |x| < \frac{1}{k} \\ 0, & |x| > \frac{1}{k} \end{cases} \tag{3.2}$$

or

$$w_k(x) = \frac{k}{\pi(1 + k^2x^2)}, \tag{3.3}$$

where $k > 0$. In Fig 3.2, we see that w becomes highly concentrated at $x = 0$ when k is large.

If we let $k \rightarrow \infty$, then the mass distribution approaches our idea of a point mass at $x = 0$. Calling this $\delta(x)$, then

$$\delta(x) = \lim_{k \rightarrow \infty} w_k(x) \tag{3.4}$$

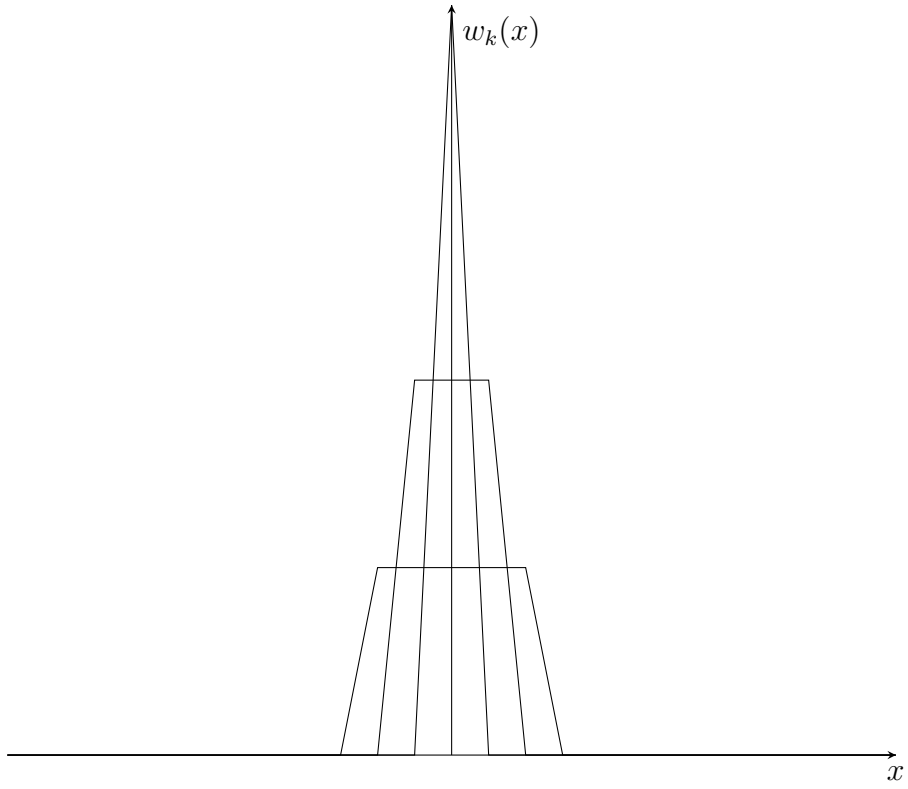

Figure 3.1: Mass Density; eq 3.2

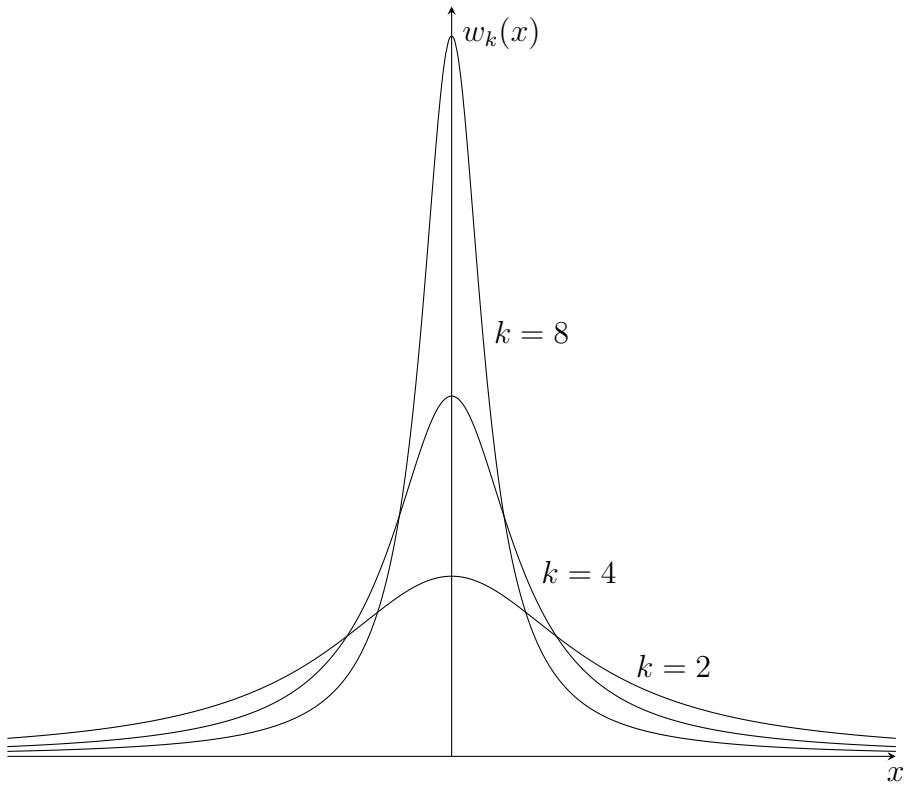

Figure 3.2: Mass Density; eq. 3.3

This definition feels intuitive, but it is not a rigorous definition of the delta function because the limit is infinite for $x = 0$. We can instead define the delta function in the following way.

$$\int_{-\infty}^{\infty} h(x)\delta(x)dx = \lim_{k \rightarrow \infty} \int_{-\infty}^{\infty} h(x)w_k(x)dx \quad (3.5)$$

This way of defining the delta function is more rigorous while still being intuitive because it is related to our understanding of delta sequences.

Assertion 3.1. *If $w(x)$ is a non-negative function that satisfies $\int_{-\infty}^{\infty} wdx = 1$ and $w(x) = O(1/x^{1+\alpha})$ where $\alpha > 0$ as $x \rightarrow \infty$ then $kw(kx)$ is a δ - sequence*

3.2 Delta as a Generalized Function

Definition An interval is closed if it includes its endpoints.

Definition A function has compact support if the subset of its domain for which its range is non-zero is closed and bounded.

Definition Generalized functions are linear functionals that are continuous on the set of infinitely differentiable functions with compact support such that all generalized functions have derivatives which are also generalized functions.

The delta function is more appropriately defined as a generalized function. To understand this way of defining δ , consider the following functional,

$$\mathcal{F}(h) = \int_{-\infty}^{\infty} g(x)h(x). \quad (3.6)$$

This functional assigns a numerical value, $\mathcal{F}(h)$, for each function h within the domain, \mathcal{D} , of \mathcal{F} . We will take \mathcal{D} to be the set of all functions that are defined over $-\infty < x < \infty$, are infinitely differentiable, and approach zero outside of some finite interval,

Suppose $\mathcal{F}(h)$ is the integral of h from ξ to ∞ .

$$\int_{-\infty}^{\infty} g(x)h(x)dx = \int_{\xi}^{\infty} h(x)dx \quad (3.7)$$

Then, $g(x)$ must be the Heaviside step function,

$$H(x) = \begin{cases} 1, & x > 0 \\ 0, & x < 0 \\ \frac{1}{2}, & x = 0 \end{cases} \quad (3.8)$$

which is a function in the classical sense. ²

²I have defined $H(0)$ to be $\frac{1}{2}$, which is the most commonly accepted value. However, for our purposes, the value at any particular point is not important since we are only ever interested in integrating the function.

If $\mathcal{F}(h)$ is $h(0)$ so that

$$\int_{-\infty}^{\infty} g(x)h(x)dx = h(0) \quad (3.9)$$

then it can be shown that there is no function, $g(x)$, which exists such that equation (3.9) is true for all functions, $h(x)$, in the domain, \mathcal{D} . We call g defined by equation (3.9) a generalized function, and in particular, it is the delta function. As such, δ is defined in the following way.

$$\int_{-\infty}^{\infty} \delta(x)h(x)dx = h(0) \quad (3.10)$$

Although $\delta(x)$ acts at $x = 0$, it can be adjusted to act at any point by shifting the argument. Thus, $\delta(x - \xi)$ acts at $x = \xi$,

$$\int_{-\infty}^{\infty} \delta(x - \xi)h(x)dx = h(\xi). \quad (3.11)$$

As a generalized function, δ is also differentiable. By referring to (3.5), one can see that defining the derivative of a generalized function involves determining the functional, $\mathcal{F}(h)$ for

$$\int_{-\infty}^{\infty} g'(x)h(x)dx = \mathcal{F}(h). \quad (3.12)$$

Integrating by parts

$$\int_{-\infty}^{\infty} g'(x)h(x)dx = g(x)h(x) \Big|_{-\infty}^{\infty} - \int_{-\infty}^{\infty} g(x)h'(x)dx. \quad (3.13)$$

The integral term is fairly simple to interpret since it is of the same form as (3.5), but the boundary term is not as nice because it involves knowing the values of g . However, our restriction that h has compact support means that it must vanish at infinity, and since we are integrating from $-\infty$ to ∞ , the boundary term must be zero.

$$\int_{-\infty}^{\infty} g'(x)h(x)dx = - \int_{-\infty}^{\infty} g(x)h'(x)dx \quad (3.14)$$

For the delta function, this means

$$\begin{aligned} \int_{-\infty}^{\infty} \delta'(x - \xi)h(x)dx &= - \int_{-\infty}^{\infty} \delta(x - \xi)h'(x)dx \\ &= -h'(\xi). \end{aligned} \quad (3.15)$$

Theorem 3.2. *The j th derivative of the delta function is defined by*

$$\int_{-\infty}^{\infty} \delta^{(j)}(\xi - x)h(\xi)d\xi = (-1)^j h^{(j)}(x). \quad (3.16)$$

Proof 3.1

Base case: Proven to be true for $j = 1$ in equation (3.15).

Induction step: Let $k \in \mathbb{N}$ and suppose theorem 3.2 is true for $j = k$. Then

$$\begin{aligned}
\int_{-\infty}^{\infty} \delta^{(k+1)}(\xi - x)h(\xi)d\xi &= \delta^{(k)}(\xi - x)h(\xi) \Big|_{-\infty}^{\infty} - \int_{-\infty}^{\infty} \delta^{(k)}(\xi - x)h'(\xi)d\xi \\
&= - \int_{-\infty}^{\infty} \delta^{(k)}(\xi - x)h'(\xi)d\xi \\
&= -(-1)^k (h')^{(k)}(x) \\
&= (-1)^{k+1} h^{(k+1)}(x)
\end{aligned}$$

■

Note that because of the discontinuity in $H(x - \xi)$ at the point $x = \xi$, the derivative of H does not exist as an ordinary function, but using the previous method does allow us to find $H'(x - \xi)$ as a generalized function,

$$\begin{aligned}
\int_{-\infty}^{\infty} H'(x - \xi)h(x)dx &= - \int_{-\infty}^{\infty} H(x - \xi)h'(x)dx \\
&= - \int_{\xi}^{\infty} h'(x)dx = h(\xi)
\end{aligned} \tag{3.17}$$

and because

$$\int_{-\infty}^{\infty} \delta(x - \xi)h(x)dx = h(\xi) \tag{3.18}$$

it must be the case that, in the sense of generalized functions,

$$H'(x - \xi) = \delta(x - \xi). \tag{3.19}$$

Such equalities between generalized functions, as seen in (3.18), are understood in the sense that if some h in \mathcal{D} is multiplied through, and we integrate over $(-\infty, \infty)$ then the result will be consistent. To wit, we consider generalized functions to be equal if

$$\int_{-\infty}^{\infty} g_1(x)h(x)dx = \int_{-\infty}^{\infty} g_2(x)h(x)dx. \tag{3.20}$$

As a final aside, notice that

$$x\delta(x) = 0 \tag{3.21}$$

as a result of

$$\int_{-\infty}^{\infty} x\delta(x)h(x)dx = [xh(x)]|_{x=0} = 0. \tag{3.22}$$

4 The Method of Green's Functions

A Green's function is the solution to a differential equation of the form

$$\mathbf{L}^*G = \delta. \tag{4.1}$$

By making use of some of the delta function's unusual properties, Green's functions can be used to solve nonhomogeneous linear differential equations.

To find the solution to the linear differential equation

$$\mathbf{L}u = \phi, \quad (4.2)$$

we start by finding the formal adjoint as in equation (2.1). If instead of v , we use G to represent the Green's function, and we replace x with a dummy variable ξ , we are left with an equation of the form

$$\int_a^b G(\xi, x) \mathbf{L}u(\xi) d\xi = [\cdots] \Big|_a^b + \int_a^b u(\xi) \mathbf{L}^* G(\xi, x) d\xi. \quad (4.3)$$

It follows from equation (4.1) that we can replace $\mathbf{L}^* G$ with δ , and from equation (4.2) that we can replace $\mathbf{L}u$ with ϕ .

$$\begin{aligned} \int_a^b G(\xi, x) \phi(\xi) d\xi &= [\cdots] \Big|_a^b + \int_a^b u(\xi) \delta(\xi - x) d\xi \\ &= [\cdots] \Big|_a^b + u(x). \end{aligned} \quad (4.4)$$

Therefore, if we choose boundary conditions for G such that the boundary terms do not depend on u and we are able to find G , then finding u is reduced to a problem of integrating $G\phi$.

To illustrate the key ideas of the method, we will consider several examples which begin simply and become more complex. Each example will be concerned with a key concept in implementing the method of Green's functions.

Example 4.2 *Loaded String*

Consider the boundary value problem

$$u''(x) = \phi(x); \quad u(0) = u(1) = 0 \quad (4.5)$$

where $\phi(x)$ is prescribed. **EXPLAIN LOADED STRING WITH DIAGRAM.**

We must first find the formal adjoint \mathbf{L}^* as in equation (4.3).
