1 Introduction

The first part of this text is primarily concerned with solutions to differential equations of the form

$$Lu = \phi \tag{1.1}$$

over an interval $a \leq x \leq b$ and subject to boundary conditions $\{B_1, \ldots, B_n\}$, where L is an nth order linear ordinary differential operator. For L to be linear it must satisfy the condititon

$$L(\alpha v + \beta w) = \alpha L v + \beta L w \tag{1.2}$$

for arbitrary functions v and w, with α and β being constant. For this condition to be met L must be of the form

$$L = a_0(x)\frac{d^n}{dx^n} + a_1(x)\frac{d^{n-1}}{dx^{n-1}} + \cdots + a_n(x) \tag{1.3}$$

The boundary conditions are linear functionals of the form

$$B_j(u) = c_j; \qquad j = 1, 2, \ldots, n \tag{1.4}$$

where c_j is an arbitrary constant.

A functional, as used here, is a transformation from function space to the real numbers. As an example

$$B(u) = u(0) = 0 \tag{1.5}$$

is a simple boundary condition for a 1st order differential operator. Specifically, our B_j's will be limited to linear combinations of u and it's derivatives up to order $n-1$. These boundary conditions have the same linearity conditons palce on them as L.

2 The Adjoint Operator
